

**Learning Haskell.** For programmers, there is a self study course at <https://github.com/system-f/fp-course>. If you want a gentle video class for beginners, you could try the class by Andres Löh, Introduction to Haskell. If you want an even gentler video class, you could try the class by Tea Leaves, Haskell for dilettantes, which works through some of class materials from Joachim Breitner's UPenn class CS194.

**Installing Haskell.** On linux or mac, install Haskell with ghcup, from

```
https://www.haskell.org/ghcup/install/
```

Then you can upgrade and check the installation with

```
% ghcup upgrade
% ghcup tui
```

In the tui display, one check means installed, two checks mean set for use. Generally, I set the versions listed as 'recommended' in that display. See <https://www.haskell.org/ghcup/steps/> on using external packages in `ghci`, etc. (On windows-11, I was able to install ghcup on windows subsystem ubuntu, just as in a standard linux, after first installing: build-essential findutils binutils curl gcc g++ libgmp-dev libc-dev libffi-dev make musl-dev ncurses-dev perl tar xz-utils.)

**Optional: Literate Haskell** To process literate Haskell files (\*.lhs), install `lhs2TeX` and `unlit`, used to produce this documentation:

```
% stack install unlit
% stack install lhs2tex
```

Then `unlit` produces Haskell (\*.hs) from literate Haskell (\*.lhs). For the `installingHaskellEtc.lhs` file I am editing now,

```
% unlit -i installingHaskellEtc.lhs -o installingHaskellEtc.hs
```

For code documentation, line-by-line, `lhs2tex` produces a latex file for generating pdf, the pdf which you are presumably looking at now. This file, `installingHaskellEtc.pdf`, is produced and opened with these steps:

```
% lhs2tex -o installingHaskellEtc.tex installingHaskellEtc.lhs
% pdflatex -shell-escape installingHaskellEtc.tex
% open installingHaskellEtc.pdf
```

Here in the pdf format, the Haskell code which is now in `installingHaskellEtc.hs` looks like this:

```
main :: IO ()
main = putStrLn "Hello, world!"
```

For code publication, the Haskell code in `installingHaskellEtc.hs` can be much more colorful and perhaps more beautiful with `minted`:

```
main :: IO ()
main = putStrLn "Hello, world!"
```

The `-shell-escape` flag for `pdflatex` is required to use the `minted` package.

**Run the program!** using one of these:

```
% runghc installingHaskellEtc.hs

% ghc installingHaskellEtc.hs -o hello
% ./hello

% ghci
ghci> :l installingHaskellEtc
ghci> main
```

**Optional: emacs with haskell language server.** This is the development environment I prefer. After installing a recent version of emacs, inside emacs, I use package-install to install: “haskell-mode“ Then I get an easy connection with language servers for syntax highlighting, code completion, etc. by adding the eglot initialization recommended here:

<https://haskell-language-server.readthedocs.io/en/latest/configuration.html#emacs>

**Optional: tmux+neovim with haskell language server** Nvim also provides easy connection with language servers for syntax highlighting, code completion, etc. Tmux allows you to split screen to run editor plus session (plus anything else) all at once, with easy switching. The combination is a very flexible and extensible IDE, developed recently.

**Ubuntu nvim** Intro youtube vids, useful for those not already familiar with nvim and tmux:

- “Dreams of Code” vid on nvim config and basics
- “Dreams of Code” vid on tmux config and basics

On Ubuntu 24.04, I installed a nerdfont, ripgrep, tmux, tmux package manager (tpm), etc

```
% sudo apt install ripgrep
% sudo apt install nodejs npm
% sudo apt install luarocks
% sudo apt install tmux
% git clone https://github.com/tmux-plugins/tpm ~/.tmux/plugins/tpm
% wget -P ~/.local/share/fonts https://github.com/ryanoasis/nerd-fonts/releases/latest/download/Meslo.zip
% cd ~/.local/share/fonts
% unzip Mezlo.zip
% rm Mezlo.zip
% sudo fc-cache -fv
% sudo npm i -g hls
% sudo npm i -g pyright
% ghcup install hls
% sudo luarocks install haskell-tools
% stack install haskell-dap ghci-dap haskell-debug-adapter
```

Then in a terminal window, in text settings, I selected the Meslo mono font. Then following the instructions here:

<https://nvchad.com/docs/quickstart/install/>

In nvim, when running

```
:MasonInstallAll,
```

you can scroll down to install haskell-language-server and pyright (and whatever else you want). And in nvim, add syntax highlighting for whatever languages you want:

```
:TSInstall haskell
:TSInstall python
:TSInstall texlab
```

Then add these lines to `.config/nvim/init.lua`:

```
require 'lspconfig'.pyright.setup{}
require 'lspconfig'.hls.setup{}
```

And in that same file, inside `require("lazy").setup({ ...})` add

```
{
  'mrcjkb/haskell-tools.nvim',
  version = '^3', -- Recommended
  lazy = false, -- This plugin is already lazy
},
```

Then create dir and file `~/.config/nvim/after/ftplugin/haskell.lua` with contents:

```
-- ~/.config/nvim/after/ftplugin/haskell.lua
local ht = require('haskell-tools')
local bufnr = vim.api.nvim_get_current_buf()
local opts = { noremap = true, silent = true, buffer = bufnr, }
-- haskell-language-server relies heavily on codeLenses,
-- so auto-refresh (see advanced configuration) is enabled by default
vim.keymap.set('n', '<space>cl', vim.lsp.codelens.run, opts)
-- Hoogle search for the type signature of the definition under the cursor
vim.keymap.set('n', '<space>hs', ht.hoogle.hoogle_signature, opts)
-- Evaluate all code snippets
vim.keymap.set('n', '<space>ea', ht.lsp.buf_eval_all, opts)
-- Toggle a GHCi repl for the current package
vim.keymap.set('n', '<leader>rr', ht.repl.toggle, opts)
-- Toggle a GHCi repl for the current buffer
vim.keymap.set('n', '<leader>rfr', function() ht.repl.toggle(vim.api.nvim_buf_get_name(0)) end, opts)
vim.keymap.set('n', '<leader>rq', ht.repl.quit, opts)
```

**Mac nvim** On Mac, first,

- At the time of this writing (May 2024) something is very wrong with the lua screen and color control for my default Mac terminal, so I installed the kitty terminal, tmux, etc:

```
brew install kitty tmux tpm
```

- I installed all the homebrew nerd fonts:

```
brew tap homebrew/cask-fonts
brew search '/font-.*-nerd-font/' \ensuremath{\backslash Varid{awk}};\text{\ttfamily '\char123 ~print~\char125 '}} xargs -I{} brew install --cask {}
```

- I installed ripgrep, haskell-language-server, debug tools

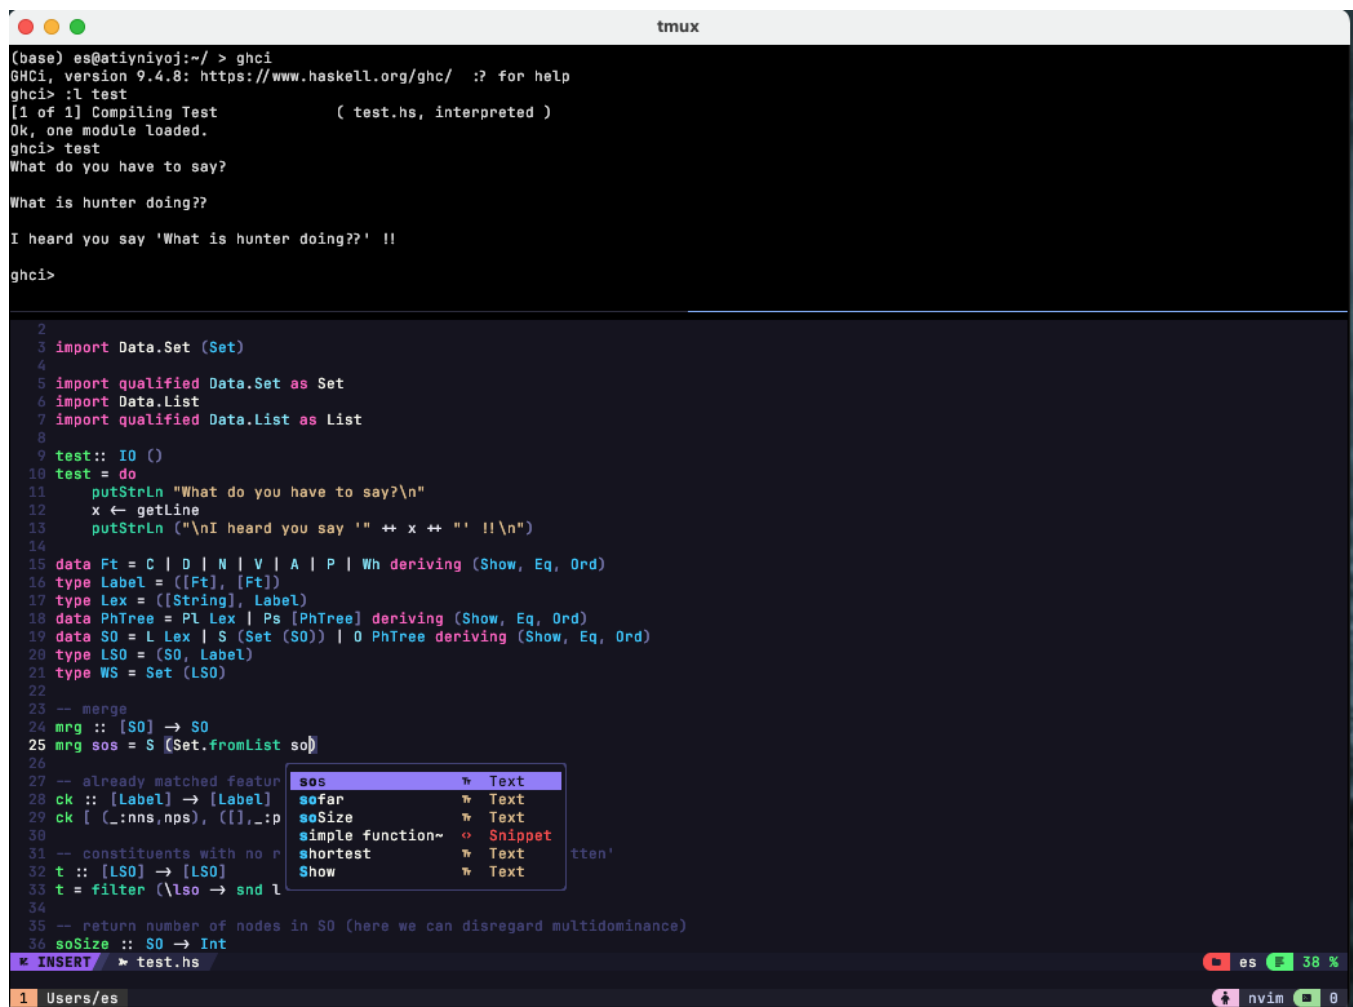

```
brew install ripgrep
ghcup install hls
stack install haskell-dap ghci-dap haskell-debug-adapter
```

- Opening a kitty terminal, in settings, I add

```
font_family      JetBrainsMono Nerd Font Mono
bold_font        JetBrainsMono Nerd Font Mono ExtraBold
bold_italic_font JetBrainsMono Nerd Font Mono ExtraBold Italic
```

Then, closing and reopening, in a kitty terminal, I set up the NvChad configuration following the suggestions used on the webpage mentioned above, here, and then tell nvim to do syntax highlighting, add lines to `init.lua`, create `haskell.lua` as described for Ubuntu, above.

Then start tmux in terminal; split screen into 2 panes; start nvim in one of them; write, edit, save code in nvim; run code in the other pane as it is developed. An alternative that avoids learning how tmux works is just to use nvim (with the NvChad configuration), opening a terminal inside nvim with `⌘h`.

The screenshot shows a tmux window with two panes. The top pane is a terminal running GHCi, and the bottom pane is an nvim editor showing Haskell code. The code defines a parser for a simple language with features like sets, lists, and a merge function. A tooltip is visible over the `sos` variable, showing its type and value.

```
(base) es@atiynioj:~/ > ghci
GHCi, version 9.4.8: https://www.haskell.org/ghc/  :? for help
ghci> :l test
[1 of 1] Compiling Test          ( test.hs, interpreted )
Ok, one module loaded.
ghci> test
What do you have to say?

What is hunter doing??

I heard you say 'What is hunter doing??' !!
ghci>
